Abstract

Bartnik's definition of gravitational quasilocal energy is analyzed. For a wide class of systems Bartnik's function is given by the ADM mass of some vacuous extension. As an example we calculate mass of a non central ball in Schwarzschild geometry. The ratio mass to volume becomes singular in the limit of small volumes.

One of the still unsolved issues of classical gravitation is a problem of the quasilocal measure of gravitational energy. Although from the formal point of view there is no need to introduce such quantity in a framework of general relativity there has been made a great effort [1][2] to construct mass function which interpolates between the local energy - momentum tensor and the global ADM mass [3]. One of possible motivations of these investigations follows from the desire to find tools which would support the formulation of conditions of the gravitational collapse [4]. Difficulties in the construction of theorems which diagnose the existence of horizons are mainly connected with the absence of concepts of a quasilocal mass and a size of the configuration.

It seems that until now the best candidate for the definition of quasilocal energy is a proposal of Bartnik [2]. In the case of a time-symmetric hypersurface Bartnik's mass is defined as follows. Let us consider the class of Riemannian three manifolds:

$$\mathcal{PM} = \{(M, g) : (M, g) \text{ is an asymptotically flat time-symmetric initial data set, satisfying the weak energy condition and such } M \text{ has no horizons}\}$$

Mass of a domain Ω (with $\partial\Omega$ connected) is defined as the infimum of ADM masses of all possible (physical) **extensions** of Ω .

$$m_B(\Omega) = \inf\{m_{ADM}(\tilde{M}) : \Omega \subset \tilde{M} \in \mathcal{PM}\}$$

The no-horizon condition was imposed originally by Bartnik to exclude explicit examples of solutions constructed in such a way that the ADM mass becomes arbitrary small. Physically these solutions correspond to systems which are formed by adding a matter inside the horizon. Such operation decreases both the area of the horizon and the ADM mass.

In this paper we prove that the Bartnik's quasilocal energy of conformally flat domain Ω is given by the ADM mass of some C^0 extension $\tilde{M}_{cfv}$ which is conformally flat and **vacuous outside** Ω . Therefore in a wide class of applications it is sufficient to analyze only vacuous extensions. This conjecture was originally formulated in [2]. Another issue is to choose the specific vacuous conformally flat extension which does not contain horizons and minimizes the ADM mass. We solve this problem on an explicit example in the

Schwarzschild geometry. We calculate the quasilocal energy of gravitational field enclosed in a non central small ball which is a part of the spacelike hypersurface in the Schwarzschild solution. However the presented technique is entirely general and can be implemented for any conformally flat subset Ω of arbitrary geometry.

In the below two theorems there is considered wider then $\mathcal{PM}$ class of extensions in which the presence of horizons is allowed:

$\mathcal{PMW} = \{(\mathcal{M}, \cdot) : (\mathcal{M}, \cdot) \text{ is an asymptotically flat time-symmetric initial data set, satisfying the weak energy condition.}\}$

We temporarily skip the problem of horizons and show that in $\mathcal{PMW}$ for any "massive" extension $\widetilde{M}(\mu)$ (μ denotes matter density) there exist some vacuous (outside Ω) extension $\widetilde{M}(\mu = 0)$ which has the ADM mass is not greater then mass of $\widetilde{M}(\mu)$. Therefore evaluation of Bartnik's mass function reduces to comparing ADM masses of vacuous extensions which have no horizons. In the case of conformal flatness different vacuous extensions are parameterized by the value of conformal factor at infinity. Finally on the example of Schwarzschild geometry we will present the method of comparing the ADM masses of extensions with different asymptotics.

As it was suggested by Bartnik the original definition may be specialized by the assumption of some additional properties of Ω and $\mathcal{PM}$ (axial or spherical symmetry, some curvature conditions etc.). In the following theorem we assume such kind of specialization.

Theorem 1. Assume conformal flatness Ω and $\mathcal{PMW}$. For any extension $\widetilde{M}(\mu_1)$ there exist some vacuous extension $\widetilde{M}(\mu = 0)_{cfv}$ which has the ADM mass not greater then ADM mass of $\widetilde{M}(\mu_1)$: $m_1 \geq m_{cfv}$.

Proof. Because of conformal flatness three dimensional line element may be written as:

$$g_{ik} = \Phi^4 h_{ik}, \quad (1)$$

where h_{ik} denotes cartesian flat metric. The constraint equations $G_{0\mu} = 0$ on a time-symmetric slice (i.e. $K_{ij} = 0$) reduce to the hamiltonian constraint:

$$\nabla^2 \Phi = -2\pi\mu\Phi^5, \quad (2)$$

The weak energy condition implies that matter density μ is nonnegative; $\mu \geq 0$. Asymptotically solution is flat: $\Phi \rightarrow A + \frac{B}{2r} + O(1/r^2)$, where positive constants A and B define the ADM mass of the system:

$$m_{ADM} = AB. \quad (3)$$

Conformal factor Φ is uniquely determined by matter distribution μ , constant A and the boundary condition on $\partial\Omega$. Therefore we designate different extensions by specifying μ and A : $\widetilde{M}(\mu, A)$ (boundary condition on $\partial\Omega$ is the same for all extensions). Let us study an arbitrary conformally flat extension $\widetilde{M}(\mu_1, A_1) \in \mathcal{PMW}$. We will construct a conformally flat vacuum extension $\widetilde{M}(\mu = 0, A_2)_{cfv} \in \mathcal{PMW}$ which has the ADM mass not greater than ADM mass of $\widetilde{M}(\mu_1, A_1)$. For $\widetilde{M}(\mu_1, A_1)$ we have

$$\nabla^2 \Phi_1 = -2\pi\mu_1\Phi_1^5, \quad (4)$$

For conformally flat vacuum extension $\widetilde{M}(\mu = 0, A_2)_{cfv}$ constraints reduce to

$$\nabla^2 \Phi_{cfv} = 0. \quad (5)$$

By the definition the geometry of Ω is fixed but we have a freedom of determining the constant A_2 at infinity. Let us choose $A_2 = A_1$. Thus the difference

$$\chi = \Phi_1 - \Phi_{cfv} \quad (6)$$

must vanish on $\partial\Omega$ and at infinity. Subtracting equations (4) and (5) we get

$$\nabla^2 \chi = -2\pi\mu_1\Phi_1^5.$$

Because of the nonnegativity of matter density function χ is superharmonic: $\nabla^2 \chi \leq 0$. From min-max principle [5] we know that superharmonic function attains its infimum on the boundary (in our case on $\partial\Omega$ or at infinity). On the boundary χ equals zero therefore in domain $R^3 - \Omega$ function χ has to be nonnegative and $\Phi_1 \geq \Phi_{cfv}$. Using the fact that the constant A is the same for both Φ_1 and Φ_{cfv} we get $B_1 \geq B_{cfv}$ and from (3):

$$m_1 \geq m_{cfv}.$$

What ends the proof.

We suppose that the statement of the theorem is also true for more general geometries. Below we study a class of extensions which is in some of sense "orthogonal" to the case of conformal flatness.

Assume that Ω is conformally flat and let us restrict to axially symmetric Ω and $\mathcal{PMW}$ (we **do not assume conformal flatness of $\mathcal{PMW}$**). General form of the axially symmetric three dimensional line element is following [6]:

$$ds^2 = \Phi^4(r, \vartheta)(e^{2q(r, \vartheta)}(dr^2 + r^2 d\vartheta^2) + r^2 \sin^2 \vartheta d\varphi^2).$$

The constraint equation now has the form

$$\nabla^2 \Phi = -f\Phi - 2\pi\mu\Phi^5 e^{2q}, \quad (7)$$

where

$$f = \frac{1}{4} \left(\frac{\partial^2 q}{\partial r^2} + \frac{1}{r} \frac{\partial q}{\partial r} + \frac{1}{r^2} \frac{\partial^2 q}{\partial \vartheta^2} \right).$$

Regularity of the metric on the axis $\vartheta = 0$ implies the following boundary conditions for Φ and q [6]:

$$\begin{aligned} \frac{\partial \Phi}{\partial \vartheta}(\vartheta = 0, r) &= 0, \\ \frac{\partial q}{\partial \vartheta}(\vartheta = 0, r) &= 0, \\ q(\vartheta = 0, r) &= 0. \end{aligned}$$

An identical set of conditions must hold for $\vartheta = \pi$. Asymptotically we still set $\Phi \rightarrow A + \frac{B}{2r} + O(1/r^2)$ and additionally $q \rightarrow O(1/r^2)$. Summarizing, if we have a function q , matter distribution μ , constant A and boundary condition on $\partial\Omega$ then f and Φ are uniquely determined. Now the extensions are designated by $\widetilde{M}(q, \mu, A)$.

We define a class of strongly nonconformally flat extensions in which the influence of q and source $f\Phi$ can be large enough to produce a closed equipotential surface $\Phi = \text{const}$.

Definition. Extension $\widetilde{M}(q, \mu, A)$ is **strongly nonconformally flat** if there exist an equipotential surface $\Phi = \text{const}$ which encloses the support of function f in such a way that:

- volume V inside $\Phi = \text{const}$ does not have common points with Ω (see picture),

- derivative in direction normal to this surface does not have zero points: $n^i \partial_i \Phi|_{\partial V} \neq 0$. n^i denotes normal unit vector.

The above two conditions intuitively mean that gravitational field in the volume V (where geometry is not conformally flat) is strong. It occurs that nonconformal extensions are more massive than conformally flat vacuum ones.

Theorem 2. Assume that Ω and $\mathcal{PMW}$ are axially symmetric and Ω is conformally flat. For any strongly nonconformally flat extension $\widetilde{M}(q_1, \mu_1, A_1)$ there exist a conformally flat vacuum extension $\widetilde{M}(q = 0, \mu = 0, A_1)$ which has the ADM mass not greater than mass of $\widetilde{M}(q_1, \mu_1, A_1)$.

Proof. Equation (7) may be rewritten in the form:

$$\nabla^2 \log \Phi_1 = -f_1 - 2\pi\mu_1 \Phi_1^4 e^{2q_1} - (\nabla \log \Phi_1)^2.$$

Integrate the above formula over volume V :

$$\int_{\partial V} \frac{n^i \partial_i \Phi_1}{\Phi_1} d^2 S = - \int_V [f_1 + 2\pi\mu_1 \Phi_1^4 e^{2q_1} + (\nabla \log \Phi_1)^2] dV.$$

It can be easily checked that $\int_V f_1 dV = 0$ (see [6]). The last two terms are nonnegative. From the other side we can use the condition that Φ_1 is constant on ∂V . Hence

$$\int_{\partial V} \frac{n^i \partial_i \Phi_1}{\Phi_1} dS^2 = \frac{1}{\Phi_1} \int_{\partial V} n^i \partial_i \Phi_1 d^2 S \leq 0.$$

Because $n^i \partial_i \Phi|_{\partial V}$ does not have zero points therefore the last inequality implies that $n^i \partial_i \Phi|_{\partial V} \leq 0$

Now we construct an extension $\widetilde{M}(q = 0, \mu_2, A_1)$ which is conformally flat and has the same ADM mass as $\widetilde{M}(q_1, \mu_1, A_1)$. Outside V (in domain of conformal flatness) we choose $\widetilde{M}(q = 0, \mu_2, A_1)$ in such a way that it is identical with original extension $\widetilde{M}(q_1, \mu_1, A_1)$ (this ensure the equality of ADM masses). Inside V we put $q = f = 0$ and $\Phi = \Phi(\partial V) = \text{const}$. Using eq.(7) one easy finds that condition $n^i \partial_i \Phi|_{\partial V} \leq 0$ implies nonnegativity of matter density on ∂V . The extension $\widetilde{M}(q = 0, \mu_2, A_1)$ is conformally flat and has the same ADM mass as $\widetilde{M}(q_1, \mu_1, A_1)$. Now we can utilize the theorem 1 and conclude that there exist some conformally flat vacuous extension which is not more massive then $\widetilde{M}(q_1, \mu_1, A_1)$.

Above theorems allows to conjecture that for conformally flat Ω vacuous conformally flat extensions are less massive then other ones. Let us notice that conformal flatness may be intuitively understood as an absence of gravitational waves - a conformally flat system without matter is flat. In this meaning conformally flat vacuous extensions do not contain energy neither in the form of matter nor gravitational waves and therefore are the least massive.

Conformally flat vacuous extensions are parameterized by constant A at infinity. It further stays to single out this particular extension which has no horizons and minimalize the ADM mass.

As an example we resolve this issue in the Schwarzschild geometry. Conformal factor is defined by:

$$\Phi = 1 + \frac{m_{Sch}}{2r}.$$

We choose Ω to be a ball in a sense of background flat metric. For simplifying the calculation assume that radius Δ of Ω is much smaller than the distance R from the center of Ω to center of Schwarzschild solution. We can translate the system of coordinates to the midpoint of Ω . $(\tilde{r}, \tilde{\vartheta}, \tilde{\varphi})$ are new spherical coordinates in which the point $r = 0$ refers to $\tilde{r} = R$, $\tilde{\vartheta} = 0$. In new coordinates

$$\Phi = 1 + \frac{m_{Sch}}{2\sqrt{R^2 + \tilde{r}^2 - 2\tilde{r}R \cos \tilde{\vartheta}}}, \quad \tilde{r} \leq \Delta < R.$$

Let us now use the assumption that $\Delta \ll R$ and expand the above formula

in power series for small $\tilde{r}$.

$$\Phi = 1 + \frac{m_{Sch}}{2R} + \frac{m_{Sch}\tilde{r}}{2R^2} \cos \tilde{\vartheta} \quad (8)$$

Because of axial the symmetry and conformal flatness of Ω the assumptions of theorems are fulfilled. Hence we restrict ourselves to extensions which are vacuous and conformally flat. Thus for $\tilde{r} > \Delta$ the hamiltonian constraint reduces to the Laplace equation. Hence

$$\Phi = A + \frac{B}{2\tilde{r}} + \sum_{l=1}^{\infty} \frac{a_l P_l(\cos \tilde{\vartheta})}{\tilde{r}^{l+1}}, \quad \tilde{r} > \Delta. \quad (9)$$

Comparing the last two equations on $\tilde{r} = \Delta$ we get:

$$1 + \frac{m_{Sch}}{2R} = A + \frac{B}{2\Delta}, \quad (10)$$

$$a_1 = \frac{m_{Sch}\Delta^3}{2R^2}, \quad (11)$$

$$a_{i>1} = 0. \quad (12)$$

Let us calculate the constant A from the first of the above formulas and insert it to eq. (3).

$$m_{ADM} = B \left(1 + \frac{m_{Sch}}{2R} - \frac{B}{2\Delta} \right). \quad (13)$$

Here we use parameterization by B but it is equivalent (eq. (10)) with parameterization by A . In order to evaluate Bartnik's mass function m_B we have to determine constant B . Lower bound on B ensues from the assumption of the nonnegativity of matter density μ . The only area where μ can be apriori negative is the boundary $\partial\Omega$ (interior of Ω and extension are vacuous). In generic case on $\partial\Omega$ we obtain the shell type distribution of matter. From (2):

$$\mu = -\frac{\nabla^2 \Phi}{2\pi\Phi^5} = -\frac{\Phi'_+ - \Phi'_-}{2\pi\Phi(\Delta)^5} \delta(\tilde{r} - \Delta),$$

where Φ'_- and Φ'_+ are calculated from solution (8), (9) and the condition (12).

$$\Phi'_- = \frac{\partial\Phi(\Delta_-)}{\partial\tilde{r}} = \frac{m_{Sch} \cos \tilde{\vartheta}}{2R^2},$$

$$\Phi'_+ = \frac{\partial\Phi(\Delta_+)}{\partial\tilde{r}} = -\frac{B}{2\Delta^2} - \frac{2a_1 \cos\tilde{\vartheta}}{\Delta^3}.$$

Inserting the above formulas into equation for μ and using eq. (11) we get:

$$\mu = \frac{\frac{3m_{Sch}}{2R^2} \cos\tilde{\vartheta} + \frac{B}{2\Delta^2}}{2\pi(1 + \frac{m_{Sch}}{2R} + \frac{m_{Sch}\Delta}{2R^2} \cos\tilde{\vartheta})^5} \delta(\tilde{r} - \Delta). \quad (14)$$

μ is everywhere nonnegative if

$$B \geq \frac{3m_{Sch}\Delta^2}{R^2} = B_0. \quad (15)$$

Upper bound for B arises from the following reasoning. B and μ are constrained by the linear dependence (14). Because of the definition we assume that the analyzed extension does not contain horizons. We expect that in extensions with horizon increasing of μ (**than also** B , see eq. (14)) causes decreasing of the ADM mass (it can be checked on explicit example in spherical symmetry). Let us notice (eq.(13)) that such decreasing of mass occurs if $\frac{B}{\Delta} > 1 + \frac{m_{Sch}}{2R}$. Therefore we put

$$B \leq \Delta(1 + \frac{m_{Sch}}{2R}) = B_1.$$

One can easy find that

$$B_1 \geq B_0$$

The ADM mass is minimalized for $B = B_0$ (see eq.(13)). Inserting B_0 (eq. (15)) to (13) and omitting higher order terms in Δ/R we finally get

$$m_B = 3m_{Sch}(1 + \frac{m_{Sch}}{2R})\left(\frac{\Delta}{R}\right)^2.$$

Let us notice that the above formula does not allow to construct local energy density $m_B/Volume$ because such quantity diverges like $1/\Delta$ in each point of a manifold. In other words binding energy of gravitational field is infinite.

As a conclusion we would like to point out that in wide class of configurations the extension which minimize the ADM mass is vacuous. There was also presented the simple procedure of selecting extensions without horizons. These results suggests that in addition to mathematical elegance the definition seems also to be computable. The described approach can be applied (at least with some simple numerics) for any conformally flat volume Ω .
